

Problem Set 6

niceguy

April 27, 2023

1. List all intermolecular interactions that take place in each of the following kinds of molecules: Xe, SO₂, C₆H₅F and LiF.

Solution: Xe: Dispersion
SO₂: Dispersion, dipole-dipole
C₆H₅F: Dispersion, dipole-dipole
LiF: Dispersion, ionic

2. The compounds Br₂ and ICl have the same number of electrons, yet Br₂ melts at -7.2°C, whereas ICl melts at 27.2°C. Explain.

Solution: Br₂ is non polar, as both Br molecules are identical. ICl is polar, bound by stronger dipole-dipole forces. Therefore, ICl has a higher melting point.

3. List the types of intermolecular forces that exist between molecules or (basic units) in each of the following species:
 - (a) Benzene
 - (b) CH₃Cl
 - (c) PF₃
 - (d) NaCl
 - (e) CS₂

Solution: Dispersion; dispersion, dipole-dipole; dispersion, dipole-dipole; dispersion, ionic; dispersion

4. Two water molecules are separated by 2.76Å in air. Use equation for dipole-dipole interactions, i.e. $U = \frac{2\mu_A\mu_B}{4\pi\epsilon_0 r^3}$ to calculate the dipole interaction. The dipole moment of water is 1.82 D.

Solution:

$$U = \frac{2(1.823.336 \times 10^{-30})^2}{4\pi\epsilon_0 (2.76 \times 10^{-10})^3} = 3.15 \times 10^{-20}$$

5. Calculate the induced dipole moment of I_2 due to a Na^+ ion that is 5.0\AA away from the center of the I_2 molecule. The polarizability of I_2 is $12.5 \times 10^{-30} m^3$.

Solution:

$$\frac{\alpha q}{r^2} = \frac{12.5 \times 10^{-30} \times 1.60 \times 10^{-19}}{(5.0 \times 10^{-10})^2} = 8.01 \times 10^{-30} C m = 2.4D$$

6. Diethyl ether ($C_2H_5OC_2H_5$) has a boiling point of $34.5^\circ C$, whereas 1-butanol (C_4H_9OH) boils at $117^\circ C$. These two compounds have the same type and number of atoms. Explain the difference in their boiling points.

Solution: Diethyl ether is nonpolar, while 1-butanol is polar. The hydrogen bonds in 1-butanol raises its boiling point.

7. If water were a linear molecule

- (a) would it still be a polar
- (b) would the water molecules still be available to form hydrogen bonds with one another?

Solution: It would not be polar. However, there would still be hydrogen bonds, as the hydrogen atom and the lone pair electrons of oxygen remain.

8. Explain why ammonia is soluble in water but nitrogen trichloride is not?

Solution: Ammonia can form hydrogen bonds with water, hence it dissolves, as nitrogen bonded with hydrogen has lone pair electrons. However, nitrogen is not bonded with hydrogen in nitrogen trichloride, so it does not form hydrogen bonds with water.

9. Acetic acid is miscible with water, but it also dissolves in non polar solvents such as benzene or carbon tetrachloride. Explain.

Solution: Acetic acid can form hydrogen bonds with water ($-COOH$), yet it has a large hydrocarbon content, so it is miscible with water. In non polar solvents, it forms a dimer.
